MSSM Higgs Physics: Theoretical Developments*

S. HEINEMEYER[†]

CERN TH Division, Dept. of Physics, CH 1211 Geneva 23, Switzerland

Abstract

The corrections to the MSSM Higgs boson masses and couplings performed in this millennium are briefly reviewed. For the lightest MSSM Higgs boson mass, m_h , we list the current status of the intrinsic uncertainties (due to unknown higher-order corrections) and the parametric uncertainties (due to the imperfect experimental knowledge of the input parameters). The need for high-precision calculations in the MSSM Higgs boson sector is exemplified in a realistic example.

MSSM HIGGS PHYSICS: THEORETICAL DEVELOPMENTS

SVEN HEINEMEYER

CERN TH Division, Dept. of Physics, CH 1211 Geneva 23, Switzerland

The corrections to the MSSM Higgs boson masses and couplings performed in this millennium are briefly reviewed. For the lightest MSSM Higgs boson mass, m_h , we list the current status of the intrinsic uncertainties (due to unknown higher-order corrections) and the parametric uncertainties (due to the imperfect experimental knowledge of the input parameters). The need for high-precision calculations in the MSSM Higgs boson sector is exemplified in a realistic example.

1 Introduction

Disentangling the mechanism that controls electroweak symmetry breaking is one of the main tasks of the current and next generation of colliders. The prime candidates are the Higgs mechanism within the Standard Model (SM) or within the Minimal Supersymmetric Standard Model (MSSM)¹. Contrary to the SM, two Higgs doublets are required in the MSSM, resulting in five physical Higgs bosons: the light and heavy CP-even h and H , the CP-odd A , and the charged Higgs bosons $H^\pm$. The Higgs sector of the MSSM can be expressed at lowest order in terms of M_Z , M_A , and $\tan\beta = v_2/v_1$, the ratio of the two vacuum expectation values. The MSSM Higgs boson sector receives large corrections from SUSY-breaking effects in the Yukawa sector of the theory. The leading one-loop correction to the lightest MSSM Higgs boson mass, m_h , is proportional to m_t^4 . For instance, the leading logarithmic one-loop term (for vanishing mixing between the scalar tops) reads¹

$$\Delta m_h^2 = \frac{3G_F m_t^4}{\sqrt{2}\pi^2 \sin^2\beta} \ln\left(\frac{m_{\tilde{t}_1} m_{\tilde{t}_2}}{m_t^2}\right). \quad (1)$$

Here $m_{\tilde{t}_{1,2}}$ denote the masses of the scalar top quarks. Corrections of this kind have dramatic effects on the predicted value of m_h and many other observables in the MSSM Higgs sector. The one-loop corrections, which are known completely, can shift m_h by 50–100%. Since this shift is related to effects from a part of the theory that does not enter at tree level, corrections even of this size do not invalidate the perturbative treatment.

The large corrections to m_h have to be compared with the anticipated accuracy at future colliders. At the LHC m_h can possibly be measured down

¹We assume all parameters in the MSSM to be real.

to $\delta m_h^{\text{exp,LHC}} \approx 200$ MeV. A future e^+e^- linear collider (LC) can even go down to $\delta m_h^{\text{exp,LC}} \approx 50$ MeV.

The effect of these large corrections is two-fold. On the one hand, reliable investigations (comparisons of experimental results with theoretical predictions) require multi-loop higher-order corrections. On the other hand, the strong dependence of m_h on the whole SUSY spectrum, especially on the scalar top sector, makes m_h an extremely powerful precision observable. m_h can be used to obtain information on otherwise unknown parameters. This allows in particular to obtain indirect information on the mixing in the scalar top sector, which is very important for fits of the SUSY Lagrangian to (prospective) experimental data².

2 Recent Calculations In The MSSM Higgs Sector

Concerning the two-loop effects, their computation is quite advanced, see³ and references therein. They include the strong corrections at $\mathcal{O}(\alpha_t \alpha_s)$, and Yukawa corrections, $\mathcal{O}(\alpha_t^2)$, to the dominant one-loop $\mathcal{O}(\alpha_t)$ term, as well as the strong corrections from the bottom/sbottom sector at $\mathcal{O}(\alpha_b \alpha_s)$ in the limit of $\tan \beta \rightarrow \infty$.² For the $b/\tilde{b}$ sector corrections also an all-order resummation of the $\tan \beta$ -enhanced terms, $\mathcal{O}(\alpha_b (\alpha_s \tan \beta)^n)$, is known⁵. Most recently the $\mathcal{O}(\alpha_t \alpha_b)$ and $\mathcal{O}(\alpha_b^2)$ corrections have been derived^{6,3}. Finally a “full” two-loop effective potential calculation (including even the momentum dependence for the leading pieces) has been published⁸. However, the latter results have been obtained using a certain renormalization in which all quantities, including SM gauge boson masses and couplings, are $\overline{\text{DR}}$ parameters. This makes them not applicable in the Feynman-diagrammatic (FD) approach using the on-shell renormalization scheme, see Sect. 5.

3 Intrinsic Uncertainties

The current intrinsic error (due to unknown higher-order corrections) consists of four different pieces:

- missing momentum-independent two-loop corrections: By varying the renormalization scale at the one-loop level, these two-loop uncertainties can be estimated to be ± 1.5 GeV.^{9,4}

²For the result for arbitrary $\tan \beta$ see⁴.

³Leading corrections in the MSSM with non-minimal flavor violation have recently been obtained in⁷.

⁴We do not consider here the “full” two-loop effective potential calculation presented in⁸ for the reasons outlined above.

- missing momentum-dependent two-loop corrections: since at the one-loop level the momentum corrections are below the level of 2 GeV, it can be estimated that they stay below ± 0.5 GeV^{3,10}.
- missing 3/4-loop corrections from the $t/\tilde{t}$ sector: by applying three different methods (changing the renormalization scheme at the two-loop level; direct evaluation of the leading terms in a simplified approximation; numerical iterative solution of the renormalization group equations) these corrections have been estimated to be at about ± 1.5 GeV (see³ and references therein).
- missing 3/4-loop corrections from the $b/\tilde{b}$ sector: the corrections from the $b/\tilde{b}$ sector can be large if both, μ and $\tan\beta$ are sufficiently large. For $\mu > 0$ it can be shown⁴ that the QCD two-loop corrections give already an extremely precise result, provided that the resummation of $(\alpha_s \tan\beta)^n$ terms⁵ is taken into account. On the other hand, for $\mu < 0$ the 3-loop corrections can be up to ± 3 GeV⁴. Since the results for a_μ favor a positive μ we do not consider this possibility here.

The current intrinsic error can thus be estimated to be³

$$\delta m_h^{\text{intr, today}} \approx 3 \text{ GeV} , \quad (2)$$

depending in detail on the investigated point in the MSSM parameter space.

If the full two-loop calculation (in an FD suitable renormalization) as well as the leading 3-loop (and possibly the very leading 4-loop) corrections are available, the intrinsic error could be reduced to less than about ± 0.5 GeV. This seems to be possible within the next 5–10 years.

4 Parametric Uncertainties

The currently induced error by M_W and m_b are already almost negligible, and will be irrelevant with the future precision of these input parameters¹¹. On the other hand, m_t and α_s play a non-negligible role. Currently we have¹¹ (for a recent reevaluation leading to similar results, see¹⁰)

$$\delta m_t^{\text{exp, today}} \approx 4.3 \text{ GeV} \Rightarrow \delta m_h^{\text{para, } m_t} \approx 4 \text{ GeV} \quad (3)$$

$$\delta \alpha_s^{\text{exp, today}} \approx 0.002 \Rightarrow \delta m_h^{\text{para, } \alpha_s} \approx 0.3 \text{ GeV} \quad (4)$$

From the LC one can hope to achieve in the future

$$\delta m_t^{\text{exp, future}} \approx 0.1 \text{ GeV} \Rightarrow \delta m_h^{\text{para, } m_t} \approx 0.1 \text{ GeV} \quad (5)$$

$$\delta \alpha_s^{\text{exp, future}} \lesssim 0.001 \Rightarrow \delta m_h^{\text{para, } \alpha_s} \approx 0.1 \text{ GeV} \quad (6)$$

The error induced by the experimental uncertainties of the SUSY parameters is very difficult to estimate. It will depend substantially on the values of

the parameters realized in nature. For most of the MSSM parameter space no analysis of the anticipated experimental errors is available yet.

5 The Need For Precision

We present one example emphasizing the need for a drastic improvement in the intrinsic error of m_h (assuming that the experimental and parametric error will be well enough under control, see above). The evaluation of m_h is based on the code *FeynHiggs*^{12,13,14}. We consider the SPS 1b benchmark scenario¹⁵, where it will be very challenging to measure the trilinear Higgs-stop coupling, A_t . In Fig. 1 we show the dependence of m_h on A_t in this scenario¹¹. The band reflects the effects of parametric uncertainties of the MSSM parameters

Figure 1: The dependence of m_h within the SPS 1b scenario is shown as a function of A_t . The band reflects the effects of parametric uncertainties of the MSSM parameters (including prospective experimental errors, see text). The light shaded (green) area corresponds to $\delta m_t^{\text{exp}} = 2$ GeV, the dark shaded (blue) area to $\delta m_t^{\text{exp}} = 0.1$ GeV (see text). The possible experimental measurement of m_h is shown (including the error). Two further bands are shown, demonstrating the effect of an intrinsic error of 3 GeV (today) and 0.5 GeV (future).

(including prospective experimental errors, see also^{11,16}). The light shaded (green) area corresponds to $\delta m_t^{\text{exp}} = 2$ GeV, the dark shaded (blue) area to $\delta m_t^{\text{exp}} = 0.1$ GeV. The possible experimental measurement of m_h is shown (including the error). Two further horizontal bands are shown, demonstrating the effect of an intrinsic error of 3 GeV (today) and 0.5 GeV (future). From

the intersection of the experimental m_h determination, including the intrinsic error, with the SPS 1b band allows to determine A_t indirectly (up to a sign ambiguity, see¹⁶ for a determination of its sign). Besides the need for a precise m_t measurement, it becomes obvious that with the current intrinsic m_h uncertainty hardly any bound could be set. If, on the other hand, a reduction of the intrinsic error down to ~ 0.5 GeV could be performed, determination of A_t better than $\sim 10\%$ seems feasible.
